# Data Management Workshop for the Pelagic Ecosystems Lab and Hakai Affiliates at UBC

## Brett Johnson & Julian Gan

## 31/01/2020

## Contents

1	$\mathbf{Pre}$	-workshop material
	1.1	Objectives
<b>2</b>	Day	1 AM: Intro to R for Data Management
	2.1	Vectors and data types
		Starting with data
		Data Manipulation
	2.4	Exporting data
		Principles of tidy data
3	Day	1 PM: Intermediate Topics in R 24
	3.1	R Markdown
	3.2	Data Quality Reports
		Data Visualization Including Maps
	3.4	Dates and Times in R

# 1 Pre-workshop material

Did you successfully install and set up all the tools necessary for this workshop?

- Download Slack
- Update or install R
- Update or install R-Studio
- Update or install packages
- Get an account for the Hakai Data Portal from data@hakai.org
- Get Git and GitHub set up

#### See README

## 1.1 Objectives

The objectives of this workshop are:

- 1. Become familiar with tools to manage and analyze data efficiently
- Write code in R-Studio
- Use tidyverse, dplyr, ggplot2 and tidyr R packages to analyze your data
- Use Git and GitHub version control and a changelog
- 2. Produce well-documented tidy data-sets that have excellent provenance

- Data sets contain a change log with a version history of what has changed and the steps used to process data.
- All variables in the dataset are defined in a data dictionary
- Laboratory, and analytical methods are thoroughly described
- 3. Create reproducible analyses
- You can easily re-run your code and analysis when you get new data
- Others can easily find your code and understand the steps you took to analyze your data
- Raw data are available

## 2 Day 1 AM: Intro to R for Data Management

## 2.1 Vectors and data types

## 2.1.1 Learning Objectives

• Inspect the content of vectors and manipulate their content.

A vector is the most common and basic data type in R, and is pretty much the workhorse of R. A vector is composed by a series of values, which can be either numbers or characters. We can assign a series of values to a vector using the c() function. For example we can create a vector of animal weights and assign it to a new object weight\_g:

```
weight_g <- c(50, 60, 65, 82)
weight_g</pre>
```

```
## [1] 50 60 65 82
```

```
animals <- c("mouse", "rat", "dog")
animals</pre>
```

```
## [1] "mouse" "rat" "dog"
```

An atomic vector is the simplest R data type and is a linear vector of a single type. Above, we saw 2 of the 6 main atomic vector types that R uses: "character" and "numeric" (or "double"). These are the basic building blocks that all R objects are built from. The other 4 atomic vector types are:

- "logical" for TRUE and FALSE (the boolean data type)
- "integer" for integer numbers (e.g., 2L, the L indicates to R that it's an integer)
- "complex" to represent complex numbers with real and imaginary parts (e.g., 1 + 4i) and that's all we're going to say about them
- "raw" for bitstreams that we won't discuss further

You can check the type of your vector using the typeof() function and inputting your vector as the argument.

Vectors are one of the many data structures that R uses. Other important ones are lists (list), matrices (matrix), data frames (data.frame), factors (factor) and arrays (array).

## 2.2 Starting with data

## 2.2.1 Learning Objectives

• Describe what a data frame is.

- Load external data from a .csv file into a data frame.
- Summarize the contents of a data frame.

#### 2.2.2 Presentation of the Survey Data

We are going to use the R function download.file() to download the CSV file that contains the survey data from figshare, and we will use read\_csv() to load into memory the content of the CSV file as an object of class data.frame. Inside the download.file command, the first entry is a character string with the source URL ("https://ndownloader.figshare.com/files/2292169"). This source URL downloads a CSV file from figshare. The text after the comma ("data/portal\_data\_joined.csv") is the destination of the file on your local machine. You'll need to have a folder on your machine called "read\_data" where you'll download the file. So this command downloads a file from figshare, names it "portal\_data\_joined.csv," and adds it to a preexisting folder named "data."

You are now ready to load the data:

```
surveys <- read_csv(here("read_data", "portal_data_joined.csv"))</pre>
```

```
## Parsed with column specification:
## cols(
##
     record_id = col_double(),
##
     month = col_double(),
##
     day = col_double(),
     year = col_double();
##
##
     plot_id = col_double(),
     species_id = col_character(),
##
     sex = col character(),
##
     hindfoot_length = col_double(),
##
##
     weight = col_double(),
##
     genus = col_character(),
     species = col_character(),
##
##
     taxa = col_character(),
##
     plot_type = col_character()
## )
```

This statement doesn't produce any output because assignments don't display anything. If we want to check that our data has been loaded, we can see the contents of the data frame by typing its name: surveys.

Wow... that was a lot of output. At least it means the data loaded properly. Let's check the top (the first 6 lines) of this data frame using the function head():

```
head(surveys)
```

```
## # A tibble: 6 x 13
##
     record_id month
                             year plot_id species_id sex
                                                                hindfoot_length weight
                         day
##
         <dbl> <dbl>
                       <dbl> <dbl>
                                      <dbl> <chr>
                                                         <chr>
                                                                           <dbl>
                                                                                  <dbl>

     ... with 4 more variables: genus <chr>, species <chr>, taxa <chr>,
       plot_type <chr>
## Try also
## View(surveys)
```

#### 2.2.3 What are data frames?

Data frames are the de facto data structure for most tabular data, and what we use for statistics and plotting.

A data frame can be created by hand, but most commonly they are generated by the functions read\_csv() or read.table(); in other words, when importing spreadsheets from your hard drive (or the web).

A data frame is the representation of data in the format of a table where the columns are vectors that all have the same length. Because columns are vectors, each column must contain a single type of data (e.g., characters, integers, factors). For example, here is a figure depicting a data frame comprising a numeric, a character, and a logical vector.

We can see this when inspecting the structure of a data frame with the function str():

```
str(surveys)
```

```
Classes 'spec_tbl_df', 'tbl_df', 'tbl' and 'data.frame': 34786 obs. of 13 variables:
                            1 72 224 266 349 363 435 506 588 661 ...

##
         plot_type = col_character()
##
```

#### 2.2.4 Inspecting data.frame Objects

We already saw how the functions head() and str() can be useful to check the content and the structure of a data frame. Here is a non-exhaustive list of functions to get a sense of the content/structure of the data. Let's try them out!

- Size:
  - dim(surveys) returns a vector with the number of rows in the first element, and the number of columns as the second element (the dimensions of the object)
  - nrow(surveys) returns the number of rows
  - ncol(surveys) returns the number of columns
- Summary:
  - str(surveys) structure of the object and information about the class, length and content of each column
  - summary(surveys) summary statistics for each column

Note: most of these functions are "generic", they can be used on other types of objects besides data.frame.

## 2.2.5 Indexing and subsetting data frames

Our survey data frame has rows and columns (it has 2 dimensions), if we want to extract some specific data from it, we need to specify the "coordinates" we want from it. Row numbers come first, followed by column numbers. However, note that different ways of specifying these coordinates lead to results with different classes.

```
# first element in the first column of the data frame (as a vector)
surveys[1, 1]

## # A tibble: 1 x 1

## record_id

## <dbl>
## 1 1

# first element in the 6th column (as a vector)
surveys[1, 6]
```

```
## # A tibble: 1 x 1
##
    species_id
##
     <chr>>
## 1 NL
\# first column of the data frame (as a vector)
surveys[, 1]
## # A tibble: 34,786 x 1
##

## 4
           266
## 5
           349
           363
## 6
## 7
           435
## 8
           506
           588
## 9
           661
## 10
## # ... with 34,776 more rows
\# first three elements in the 7th column (as a vector)
surveys[1:3, 7]
## # A tibble: 3 x 1
##
   sex
##
    <chr>>
## 1 M
## 2 M
## 3 <NA>
# the 3rd row of the data frame (as a data.frame)
surveys[3, ]
## # A tibble: 1 x 13
   record_id month day year plot_id species_id sex hindfoot_length weight
        <dbl> <dbl> <dbl> <dbl> <chr> <chr>
                                                                  <dbl> <dbl>
```

: is a special function that creates numeric vectors of integers in increasing or decreasing order, test 1:10 and 10:1 for instance.

You can also exclude certain indices of a data frame using the "-" sign:

```
surveys[, -1]
                        # The whole data frame, except the first column
## # A tibble: 34,786 x 12
##
              day year plot_id species_id sex
                                                   hindfoot length weight genus
                           <dbl> <chr>
                                                                     <dbl> <chr>
##
      <dbl> <dbl> <dbl>
                                             <chr>
                                                              <dbl>

                   11
                         12 1977
                                                       <NA>
                                                                           NA
## # ... with 4 more variables: genus <chr>, species <chr>, taxa <chr>,
       plot_type <chr>
```

Data frames can be subset by calling indices (as shown previously), but also by calling their column names directly:

```
surveys["species_id"]  # Result is a data.frame
surveys[, "species_id"]  # Result is a vector
surveys[["species_id"]]  # Result is a vector
surveys$species_id  # Result is a vector
```

In RStudio, you can use the autocompletion feature to get the full and correct names of the columns.

## 2.3 Data Manipulation

#### 2.3.1 Learning Objectives

- Describe the purpose of the dplyr and tidyr packages.
- Select certain columns in a data frame with the dplyr function select.
- Select certain rows in a data frame according to filtering conditions with the dplyr function filter .
- Link the output of one **dplyr** function to the input of another function with the 'pipe' operator %>%.
- Add new columns to a data frame that are functions of existing columns with mutate.
- Use group\_by, and summarize to split a data frame into groups of observations, apply a summary statistics for each group, and then combine the results.
- Describe the concept of a wide and a long table format and for which purpose those formats are useful.
- Describe what key-value pairs are.
- Reshape a data frame from long to wide format and back with the spread and gather commands from the tidyr package.

## 2.3.2 dplyr and tidyr

Bracket subsetting is handy, but it can be cumbersome and difficult to read, especially for complicated operations. Enter **dplyr** is a package for making tabular data manipulation easier. It pairs nicely with **tidyr** which enables you to swiftly convert between different data formats for plotting and analysis.

Packages in R are basically sets of additional functions that let you do more stuff. The functions we've been using so far, like str() or data.frame(), come built into R; packages give you access to more of them. Before you use a package for the first time you need to install it on your machine, and then you should import it in every subsequent R session when you need it. You should already have installed the tidyverse package. This is an "umbrella-package" that installs several packages useful for data analysis which work together well such as tidyr, dplyr, ggplot2, tibble, etc.

To load the package, type:

```
## load the tidyverse packages, incl. dplyr
library("tidyverse")
```

The package **dplyr** provides easy tools for the most common data manipulation tasks. It is built to work directly with data frames.

The package **tidyr** addresses the common problem of wanting to reshape your data for plotting and use by different R functions. Sometimes we want data sets where we have one row per measurement. Sometimes we want a data frame where each measurement type has its own column, and rows are instead more aggregated groups - like plots or aquaria. Moving back and forth between these formats is nontrivial, and **tidyr** gives you tools for this and more sophisticated data manipulation.

To learn more about dplyr and tidyr after the workshop, you may want to check out this handy data transformation with dplyr cheatsheet and this one about tidyr.

```
surveys <- read_csv(here("read_data", "portal_data_joined.csv"))</pre>
```

```
## Parsed with column specification:
## cols(
## record_id = col_double(),
## month = col_double(),
## day = col_double(),
## year = col_double(),
## plot_id = col_double(),
## species_id = col_character(),
```

```
##
     sex = col_character(),
##
     hindfoot_length = col_double(),
##
     weight = col double(),
     genus = col_character(),
##
##
     species = col_character(),
##
     taxa = col_character(),
     plot_type = col_character()
##
## )
## inspect the data
str(surveys)
## preview the data
# View(surveys)
```

We're going to learn some of the most common dplyr functions:

- select(): subset columns
- filter(): subset rows on conditions
- mutate(): create new columns by using information from other columns
- group\_by(): creates groups based on categorical data in a column
- summarize(): create summary statisites on grouped data
- arrange(): sort results
- count(): count discrete values

#### 2.3.3 Selecting columns and filtering rows

To select columns of a data frame, use select(). The first argument to this function is the data frame (surveys), and the subsequent arguments are the columns to keep.

```
select(surveys, plot_id, species_id, weight)
```

To select all columns except certain ones, put a "-" in front of the variable to exclude it.

```
select(surveys, -record_id, -species_id)
```

This will select all the variables in surveys except record\_id and species\_id.

To choose rows based on a specific criteria, use filter():

```
filter(surveys, year == 1995)
```

```
## # A tibble: 1,180 x 13
                          day year plot_id species_id sex
                                                                hindfoot_length weight
##

#### 2.3.4 Pipes

What if you want to select and filter at the same time? There are three ways to do this: use intermediate steps, nested functions, or pipes.

With intermediate steps, you create a temporary data frame and use that as input to the next function, like this:

```
surveys2 <- filter(surveys, weight < 5)
surveys_sml <- select(surveys2, species_id, sex, weight)</pre>
```

This is readable, but can clutter up your workspace with lots of objects that you have to name individually. With multiple steps, that can be hard to keep track of.

The a sometimes better option, *pipes*, are a recent addition to R. Pipes let you take the output of one function and send it directly to the next, which is useful when you need to do many things to the same dataset. Pipes in R look like %>% and are made available via the magrittr package, installed automatically with dplyr. If you use RStudio, you can type the pipe with Ctrl + Shift + M if you have a PC or Cmd + Shift + M if you have a Mac.

```
surveys %>%
filter(weight < 5) %>%
select(species_id, sex, weight)
```

```
## # A tibble: 17 x 3
##
      species id sex
                          weight
##
       <chr>

                   М
                                4
```

In the above code, we use the pipe to send the surveys dataset first through filter() to keep rows where weight is less than 5, then through select() to keep only the species\_id, sex, and weight columns. Since %>% takes the object on its left and passes it as the first argument to the function on its right, we don't need to explicitly include the data frame as an argument to the filter() and select() functions any more.

Some may find it helpful to read the pipe like the word "then". For instance, in the above example, we took the data frame surveys, then we filtered for rows with weight < 5, then we selected columns species\_id, sex, and weight. The dplyr functions by themselves are somewhat simple, but by combining them into linear workflows with the pipe, we can accomplish more complex manipulations of data frames.

If we want to create a new object with this smaller version of the data, we can assign it a new name:

```
surveys_sml <- surveys %>%
filter(weight < 5) %>%
```

```
select(species_id, sex, weight)
surveys_sml
```

```
## # A tibble: 17 x 3
##
       species_id sex
                          weight
##

## 15 RM
                   F
                                4
## 16 RM
                   М
                                4
## 17 RM
                   М
```

Note that the final data frame is the leftmost part of this expression.

#### 2.3.5 Challenge

Using pipes, subset the surveys data to include animals collected before 1995 and retain only the columns year, sex, and weight.

```
surveys %>%
  filter(year < 1995) %>%
  select(year, sex, weight)
```

#### **2.3.6** Mutate

Frequently you'll want to create new columns based on the values in existing columns, for example to do unit conversions, or to find the ratio of values in two columns. For this we'll use mutate().

To create a new column of weight in kg:

```
surveys %>%
mutate(weight_kg = weight / 1000)
```

```
## # A tibble: 34,786 x 14
##
      record_id month
                                year plot_id species_id sex
                                                                   hindfoot_length weight
                           day
##
           <dbl> <dbl> <dbl> <dbl> <
                                         <dbl> <chr>
                                                            <chr>>
                                                                              <dbl>
                                                                                      <dbl>

## # ... with 34,776 more rows, and 6 more variables: genus <chr>, species <chr>,
       taxa <chr>, plot_type <chr>, weight_kg <dbl>, weight_kg2 <dbl>
```

If this runs off your screen and you just want to see the first few rows, you can use a pipe to view the **head()** of the data. (Pipes work with non-**dplyr** functions, too, as long as the **dplyr** or **magrittr** package is loaded).

```
surveys %>%
  mutate(weight_kg = weight / 1000) %>%
  head()
```

```
## # A tibble: 6 x 14

                                                                                      NA
## 6
            363
                    11
                          12
                              1977
                                           2 NL
                                                         <NA>
                                                                              NA
                                                                                      NA
## # ... with 5 more variables: genus <chr>, species <chr>, taxa <chr>,
       plot_type <chr>, weight_kg <dbl>
```

The first few rows of the output are full of NAs, so if we wanted to remove those we could insert a filter() in the chain:

```
surveys %>%
  drop_na(weight) %>%
  mutate(weight_kg = weight / 1000) %>%
  head()
```

```

                                                                                     218
## # ... with 5 more variables: genus <chr>, species <chr>, taxa <chr>,
       plot_type <chr>, weight_kg <dbl>
```

drop\_na() is a function that determines whether something is an NA, and will drop the whole row if there is an NA in the column you specified (weight in this case). Using drop\_na() with no column named will look for an NA in any column and drop the whole row if there are any NAs

## 2.3.7 Challenge

Create a new data frame from the surveys data that meets the following criteria: contains only the species\_id column and a new column called hindfoot\_half containing values that are half the hindfoot\_length values. In this hindfoot\_half column, there are no NAs and all values are less than 30.

Hint: think about how the commands should be ordered to produce this data frame!

```
surveys_hindfoot_half <- surveys %>%
  drop_na(hindfoot_length) %>%
  mutate(hindfoot_half = hindfoot_length / 2) %>%
  filter(hindfoot_half < 30) %>%
  select(species_id, hindfoot_half)
```

#### 2.3.8 The summarize() function

group\_by() is often used together with summarize(), which collapses each group into a single-row summary of that group. group\_by() takes as arguments the column names that contain the categorical variables for which you want to calculate the summary statistics. So to compute the mean weight by sex:

```
surveys %>%
  group_by(sex) %>%
  summarize(mean_weight = mean(weight, na.rm = TRUE))
## # A tibble: 3 x 2
##
     sex
           mean weight
##
     <chr>>
                  <dbl>
## 1 F
                   42.2
## 2 M
                   43.0
## 3 <NA>
                   64.7
```

You may also have noticed that the output from these calls doesn't run off the screen anymore. It's one of the advantages of tbl\_df over data frame.

You can also group by multiple columns:

```
surveys %>%
  group_by(sex, species_id) %>%
  summarize(mean_weight = mean(weight, na.rm = TRUE))

## # A tibble: 92 x 3
## # Groups: sex [3]
## sex species_id mean_weight
## <chr> <chr> <dbl>
```

```

When grouping both by sex and species\_id, the last few rows are for animals that escaped before their sex and body weights could be determined. You may notice that the last column does not contain NA but NaN (which refers to "Not a Number"). To avoid this, we can remove the missing values for weight before we attempt to calculate the summary statistics on weight. Because the missing values are removed first, we can omit na.rm = TRUE when computing the mean:

```
surveys %>%
drop_na(weight) %>%
group_by(sex, species_id) %>%
summarize(mean_weight = mean(weight))
```

```
## # A tibble: 64 x 3

Here, again, the output from these calls doesn't run off the screen anymore. If you want to display more data, you can use the print() function at the end of your chain with the argument n specifying the number of rows to display:

```
surveys %>%
  filter(!is.na(weight)) %>%
  group_by(sex, species_id) %>%
  summarize(mean_weight = mean(weight)) %>%
  print(n = 15)
## # A tibble: 64 x 3
## # Groups:
               sex [3]
##
            species_id mean_weight
      sex
##
      <chr> <chr>
                              <dbl>
    1 F
                               9.16

Once the data are grouped, you can also summarize multiple variables at the same time (and not necessarily on the same variable). For instance, we could add a column indicating the minimum weight for each species for each sex:

```
surveys %>%
  filter(!is.na(weight)) %>%
  group_by(sex, species_id) %>%
  summarize(mean_weight = mean(weight),
            min_weight = min(weight))
## # A tibble: 64 x 4
## # Groups:
               sex [3]
            species_id mean_weight min_weight
##
      sex
##
      <chr> <chr>
                              <dbl>
                                          <dbl>
##
   1 F
                                9.16
            BA
                                              6
   2 F
##
            DM
                              41.6
                                             10

To sort in descending order, we need to add the desc() function. If we want to sort the results by decreasing order of mean weight:

```
surveys %>%
  filter(!is.na(weight)) %>%
  group_by(sex, species_id) %>%
  summarize(mean_weight = mean(weight),
             min_weight = min(weight)) %>%
  arrange(desc(mean_weight))
## # A tibble: 64 x 4
## # Groups:

## 2.3.9 Counting

When working with data, we often want to know the number of observations found for each factor or combination of factors. For this task, **dplyr** provides **count()**. For example, if we wanted to count the number of rows of data for each sex, we would do:

```
surveys %>%
    count(sex)

## # A tibble: 3 x 2
## sex    n
## <chr> <int>
## 1 F    15690
## 2 M    17348
## 3 <NA>    1748
```

The count() function is shorthand for something we've already seen: grouping by a variable, and summarizing it by counting the number of observations in that group. In other words, surveys %>% count() is equivalent to:

```
surveys %>%
    group_by(sex) %>%
    summarise(count = n())
## # A tibble: 3 x 2
     sex
           count
##
     <chr> <int>
## 1 F
           15690
## 2 M
           17348
## 3 <NA>
            1748
For convenience, count() provides the sort argument:
surveys %>%
    count(sex, sort = TRUE)
## # A tibble: 3 x 2
##
     sex
     <chr> <int>
##
## 1 M
           17348
## 2 F
           15690
## 3 <NA>
            1748
     2.3.10 Challenge
       1. How many animals were caught in each plot_type surveyed?
     surveys %>%
         count(plot_type)
     ## # A tibble: 5 x 2
     ##
          plot_type
                                          n
     ##
          <chr>>
                                      <int>
     ## 1 Control
                                      15611
     ## 2 Long-term Krat Exclosure
                                       5118
     ## 3 Rodent Exclosure
                                       4233
     ## 4 Short-term Krat Exclosure
                                      5906
     ## 5 Spectab exclosure
                                       3918
       2. Use group_by() and summarize() to find the mean, min, and max hindfoot length for each
         species (using species_id). Also add the number of observations (hint: see ?n).
     surveys %>%
         filter(!is.na(hindfoot_length)) %>%
         group_by(species_id) %>%
         summarize(
             mean_hindfoot_length = mean(hindfoot_length),
             min_hindfoot_length = min(hindfoot_length),
             max_hindfoot_length = max(hindfoot_length),
             n = n()
         )
     ## # A tibble: 25 x 5
     ##
           species_id mean_hindfoot_length min_hindfoot_length max_hindfoot_length
     ##
           <chr>
                                       <dbl>
                                                            <dbl>
                                                                                 <dbl> <int>
     ##
                                        33
                                                                                    35

#### Exporting data 2.4

## # ... with 17 more rows

Now that you have learned how to use dplyr to extract information from or summarize your raw data, you may want to export these new processed data sets to share them with your collaborators or for archival.

Never write to read\_data/

Similar to the read\_csv() function used for reading CSV files into R, there is a write\_csv() function that generates CSV files from data frames.

```
write_csv(surveys_sml, here("write_data", "surveys_sml.csv"))
```

- Knit your document
- Commit, Pull, Push

Questions?

## Principles of tidy data

Tidy data

1. Each variable has its own column

- 2. Each observation has its own row
- 3. Each value must have its own cell
- 4. Each type of observational unit forms a table

Sometimes your you want to spread the observations of on variable across multiple columns.

In surveys, the rows of surveys contain the values of variables associated with each record (the unit), values such the weight or sex of each animal associated with each record. What if instead of comparing records, we wanted to compare the different mean weight of each species between plots? (Ignoring plot\_type for simplicity).

We'd need to create a new table where each row (the unit) is comprised of values of variables associated with each plot. In practical terms this means the values of the species in **genus** would become the names of column variables and the cells would contain the values of the mean weight observed on each plot.

Having created a new table, it is therefore straightforward to explore the relationship between the weight of different species within, and between, the plots. The key point here is that we are still following a tidy data structure, but we have **reshaped** the data according to the observations of interest: average species weight per plot instead of recordings per date.

The opposite transformation would be to transform column names into values of a variable.

We can do both these of transformations with two tidyr functions, pivot\_wider() and pivot\_longer().

#### 2.5.1 Widening (aka. Spreading)

pivot\_wider() makes a dataset wider by increasing the number of columns and decreasing the number of rows. It takes three principal arguments:

- 1. the data
- 2. the names from column variable whose values will become the new column names.
- 3. the values from column whose values will fill the new column variables.

Further arguments include values fill which, if set, fills in missing values with the value provided.

Let's use pivot\_wider() to transform surveys to find the mean weight of each species in each plot over the entire survey period. We use filter(), group\_by(), and summarize() to filter our observations and variables of interest, and create a new variable for the mean\_weight. We use the pipe as before too.

```
surveys_gw <- surveys %>%
  filter(!is.na(weight)) %>%
  group_by(genus, plot_id) %>%
  summarize(mean_weight = mean(weight))

str(surveys_gw)

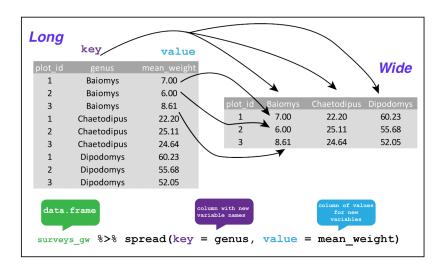

## Classes 'grouped_df', 'tbl_df', 'tbl' and 'data.frame': 196 obs. of 3 variables:
```

```
: chr "Baiomys" "Baiomys" "Baiomys" "Baiomys" ...

##
         taxa = col_character(),
##
         plot_type = col_character()
     ..)
##
    - attr(*, "groups")=Classes 'tbl_df', 'tbl' and 'data.frame':
##
                                                                   10 obs. of 2 variables:
##
     ..$ genus: chr "Baiomys" "Chaetodipus" "Dipodomys" "Neotoma" ...
     ..$ .rows:List of 10
##
##
     ....$: int 12345678
##
     ....$: int 9 10 11 12 13 14 15 16 17 18 ...
##
     ....$ : int 33 34 35 36 37 38 39 40 41 42 ...
##
     ....$ : int 57 58 59 60 61 62 63 64 65 66 ...
##
     ....$ : int 81 82 83 84 85 86 87 88 89 90 ...
##
     ....$ : int 105 106 107 108 109 110 111 112 113 114 ...
##
     ....$ : int 128 129 130 131 132 133 134 135 136 137 ...
##
     ....$ : int 152 153 154 155 156 157 158 159 160 161 ...
##
     ....$: int 176 177 178 179 180 181 182 183 184 185 ...
     ....$ : int 195 196
##
##
     ..- attr(*, ".drop")= logi TRUE
```

This yields surveys\_gw where the observations for each plot are spread across multiple rows, 196 observations of 3 variables. Using pivot\_wider() to names from genus with values from mean\_weight this becomes 24 observations of 11 variables, one row for each plot. We again use pipes:

```
surveys_wide <- surveys_gw %>%
 pivot_wider(names_from = genus, values_from = mean_weight)
str(surveys_wide)
## Classes 'tbl_df', 'tbl' and 'data.frame':
                                               24 obs. of 11 variables:
   $ plot_id
                     : num
                           1 2 3 5 18 19 20 21 4 6 ...
   $ Baiomys
                           7 6 8.61 7.75 9.5 ...
##
                     : num
##
   $ Chaetodipus
                    : num
                          22.2 25.1 24.6 18 26.8 ...
## $ Dipodomys
                    : num
                           60.2 55.7 52 51.1 61.4 ...
## $ Neotoma
                           156 169 158 190 149 ...
                    : num
## $ Onychomys
                    : num
                           27.7 26.9 26 27 26.6 ...
## $ Perognathus
                    : num 9.62 6.95 7.51 8.66 8.62 ...
## $ Peromyscus
                    : num 22.2 22.3 21.4 21.2 21.4 ...
## $ Reithrodontomys: num 11.4 10.7 10.5 11.2 11.1 ...
## $ Sigmodon
                    : num NA 70.9 65.6 82.7 46.1 ...
## $ Spermophilus
                    : num NA NA NA NA NA S7 NA NA NA ...
```

We could now plot comparisons between the weight of species in different plots, although we may wish to fill in the missing values first.

```
surveys_gw %>%
  spread(genus, mean_weight, fill = 0) %>%
  head()

                                                                                       21.8
## #
      .. with 3 more variables: Reithrodontomys <dbl>, Sigmodon <dbl>,
       Spermophilus <dbl>
```

#### 2.5.2 Lengthening (aka. Gathering)

The opposing situation could occur if we had been provided with data in the form of surveys\_spread, where the genus names are column names, but we wish to treat them as values of a genus variable instead.

In this situation we are gathering the column names and turning them into a pair of new variables. One variable represents the column names as values, and the other variable contains the values previously associated with the column names.

pivot\_longer() takes four principal arguments:

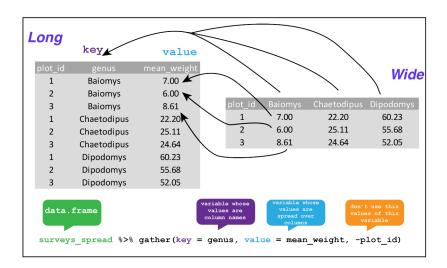

- 1. the data
- 2. the names\_to column variable we wish to create from column names.
- 3. the values to column variable we wish to create and fill with values associated with the new column.
- 4. the names of the columns we use to fill the key variable (or to drop).

To recreate surveys\_gw from surveys\_wide we would create a key called genus and value called mean\_weight and use all columns except plot\_id for the key variable. Here we drop plot\_id column with a minus sign.

```
surveys_long <- surveys_wide %>%
  pivot_longer(names_to = "genus", values_to = "mean_weight", -plot_id)

str(surveys_long)

## Classes 'tbl_df', 'tbl' and 'data.frame': 240 obs. of 3 variables:
## $ plot_id : num 1 1 1 1 1 1 1 1 1 1 1 ...
## $ genus : chr "Baiomys" "Chaetodipus" "Dipodomys" "Neotoma" ...
```

\$ mean\_weight: num 7 22.2 60.2 156.2 27.7 ...

Note that now the NA genera are included in the re-lengthened format. WIdening and then lengthening can be a useful way to balance out a dataset so every replicate has the same composition.

We could also have used a specification for what columns to include. This can be useful if you have a large number of identifying columns, and it's easier to specify what to gather than what to leave alone. And if the columns are in a row, we don't even need to list them all out - just use the : operator!

```
surveys_wide %>%
  pivot_longer(names_to = "genus", values_to = "mean_weight", Baiomys:Spermophilus) %>%
  head()
```

```
## # A tibble: 6 x 3
##
     plot_id genus
                          mean_weight
##
       <dbl> <chr>
                                 <dbl>

## 6
           1 Perognathus
                                  9.62
```

#### 2.5.3 Challenge

1. Widen the surveys data frame with year as columns, plot\_id as rows, and the number of genera per plot as the values. You will need to summarize before reshaping, and use the function n\_distinct() to get the number of unique genera within a particular chunk of data. It's a powerful function! See ?n\_distinct for more.

```
rich_time <- surveys %>%
  group_by(plot_id, year) %>%
  summarize(n_genera = n_distinct(genus)) %>%
  pivot_wider(names_from = year, values_from = n_genera)
head(rich_time)
## # A tibble: 6 x 27
## # Groups:
               plot_id [6]
     plot id `1977`
                                                                                  1986
##
                     1978
                                    `1980`
                                            `1981`
                                                   1982
                                                           1983
                                                                  1984
                                                                          1985
                              1979`

3. The surveys data set has two measurement columns: hindfoot\_length and weight. This makes it difficult to do things like look at the relationship between mean values of each measurement per year in different plot types. Let's walk through a common solution for this type of problem. First, use pivot\_longer() to create a dataset where we have a key column called measurement and a value column that takes on the value of either hindfoot\_length or weight. Hint: You'll need to specify which columns are being gathered.

```
surveys long <- surveys %>%
  pivot_longer(names_to = "measurement", values_to = "value", cols = c(hindfoot_length, weight))
```

4. With this new data set, calculate the average of each measurement in each year for each different plot\_type. Then pivot\_wider() them into a data set with a column for hindfoot\_length and weight. *Hint*: You only need to specify the key and value columns for pivot\_wider().

```
surveys_long %>%
  group by (year, measurement, plot type) %>%
  summarize(mean_value = mean(value, na.rm=TRUE)) %>%
 pivot wider(names from = measurement, values from = mean value)
## # A tibble: 130 x 4
## # Groups: year [26]
##
       year plot_type
                                     hindfoot_length weight

## 3 Day 1 PM: Intermediate Topics in R

- 3.1 R Markdown
- 3.2 Data Quality Reports
- 3.3 Data Visualization Including Maps
- 3.3.1 Plotting with ggplot2

ggplot2 is a plotting package that makes it simple to create complex plots from data in a data frame. It provides a more programmatic interface for specifying what variables to plot, how they are displayed, and general visual properties.

ggplot2 functions like data in the 'long' format, i.e., a column for every variable, and a row for every observation. Well-structured data will save you lots of time when making figures with ggplot2

ggplot graphics are built step by step by adding new elements. Adding layers in this fashion allows for extensive flexibility and customization of plots.

To build a ggplot, we will use the following basic template that can be used for different types of plots:

```
ggplot(data = <DATA>, mapping = aes(<MAPPINGS>)) + <GEOM_FUNCTION>()
```

• use the ggplot() function and bind the plot to a specific data frame using the data argument

```
ggplot(data = surveys_complete)
```

• define a mapping (using the aesthetic (aes) function), by selecting the variables to be plotted and specifying how to present them in the graph, e.g. as x/y positions or characteristics such as size, shape, color etc

```
ggplot(data = surveys_complete, mapping = aes(x = weight, y = hindfoot_length))
```

- add 'geoms' graphical representations of the data in the plot (points, lines, bars). ggplot2 offers many different geoms; we will use some common ones today, including:
  - \* `geom\_point()` for scatter plots, dot plots, etc.
  - \* `geom\_boxplot()` for, well, boxplots!
  - \* `geom\_line()` for trend lines, time series, etc.

#### Notes

- Anything you put in the ggplot() function can be seen by any geom layers that you add (i.e., these are universal plot settings). This includes the x- and y-axis mapping you set up in aes().
- You can also specify mappings for a given geom independently of the mappings defined globally in the ggplot() function.
- The + sign used to add new layers must be placed at the end of the line containing the *previous* layer. If, instead, the + sign is added at the beginning of the line containing the new layer, ggplot2 will not add the new layer and will return an error message.

#### 3.3.2 ggplot2 themes

In addition to theme\_bw(), which changes the plot background to white, ggplot2 comes with several other themes which can be useful to quickly change the look of your visualization. The complete list of themes is available at http://docs.ggplot2.org/current/ggtheme.html. theme\_minimal() and theme\_light() are popular, and theme\_void() can be useful as a starting point to create a new hand-crafted theme.

The ggthemes package provides a wide variety of options (including an Excel 2003 theme). The ggplot2 extensions website provides a list of packages that extend the capabilities of ggplot2, including additional themes.

#### **3.3.2.1** Faceting

- facet\_wrap()
- facet\_grid()

## 3.3.2.2 Arranging Multiple Plots

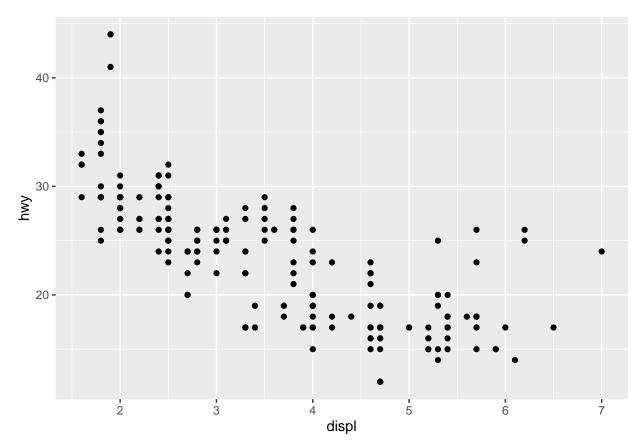

cowplot()

```
library(tidyverse)

# The tidyverse library has a data frame object called mpg, it's about cars.
# Check it out
mpg
```

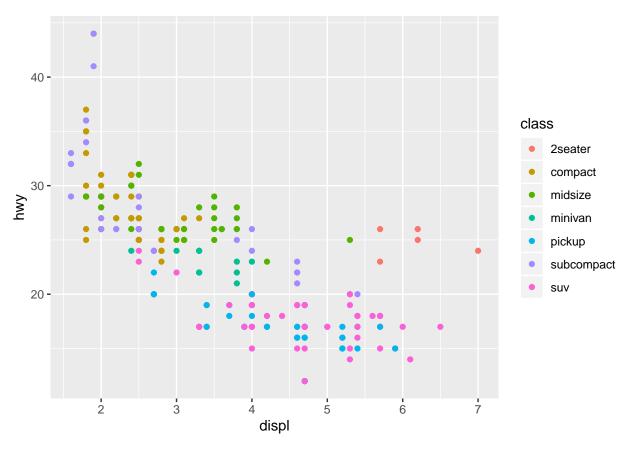

```

## 3.3.3 Site Maps

Section Contributors:

- Dr. Daniel Okamoto
- Jenn Burt

A common task amongst most field researchers is the need to make a basic site map to describe the location of your sampling. Using Arc GIS is the most common way to produce maps at Hakai, but sometimes a simple solution that could be implemented in R is desired.

For a high resolution map with the resolution needed to see detailed coastline features you can use the following code and shapefile. To get this to work on your computer, download the shape file and put it in a R Studio project sub-folder called data.

```
library(maptools)
library(rgeos)
library(rgdal)
library(ggplot2)
library(tidyverse)
library(here)
```

## 3.3.3.1 High Resolution Maps

The high resolution map used here requires that you download a set of ESRI shape files from this book's GitHUB repository. Those files can be downloaded from the 2\_Shapefile folder here. Put the 2\_Shapefile folder into the data folder of your R-Studio project.

This script assumes you are using the here() package in conjunction with R-Studio projects to obviate setting your working directory.

```
BC.shp <- readOGR(here("read_data","2_Shapefile", "COAST_TEST2.shp"))</pre>
## OGR data source with driver: ESRI Shapefile
## Source: "C:\Users\Julian\Documents\Work\Hakai\GitHub\Pelagic-Ecosystems\R-workshop\read_data\2_Shape
## with 1 features
## It has 5 fields
### chose the lat/long extent you want to show
Ncalvert <- extent(-128.18, -127.94, 51.61, 51.78)
### crop your shapefile polygons to the extent defined
# takes a moment to run (patience grasshopper)
BC.shp2 <- crop(BC.shp,Ncalvert)
### project and fortify (i.e. turn into a dataframe)
BC.df <- fortify(BC.shp2)
# (IF DESIRED) Load .csv file with your specific study site lat/longs
# this file is a dataframe with 4 columns: site_name, otterOcc(Y or N), lat, long
# EXPTsites <- read.csv("/Users/jennb/Dropbox/Simple_BC_map/EXPTsites.csv", header = T)
# Jenn graph
# here is where you can see the styles of north arrow (scroll to bottom): http://oswaldosantos.github.i
# the high resolution shape file works well at this scale as it gives lots of the coastline detail
ggplot()+ theme_bw()+
   geom_polygon(data= BC.df, aes(x=long,y=lat,group= group),
     colour= "black", size=0.1, fill='grey95')+

## ${\bf 3.3.3.2}\quad {\bf Medium\ Resolution\ PBS\ Mapping\ Package}$

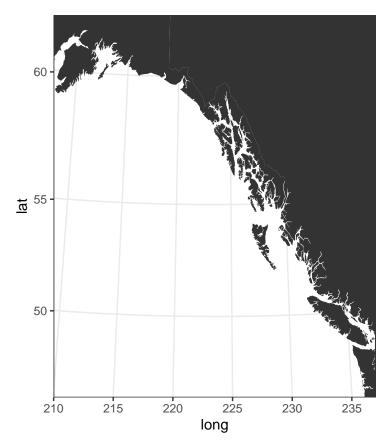

The Pacific Biological Station in Nanaimo has put together a mapping package that contains some medium resolution files of the Pacific Coast.

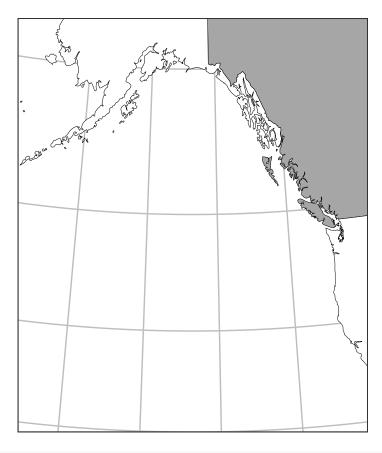

```
# # add site points
# points(EXPTsites$long, EXPTsites$lat, cex=1.5, pch=20, size=2)
```

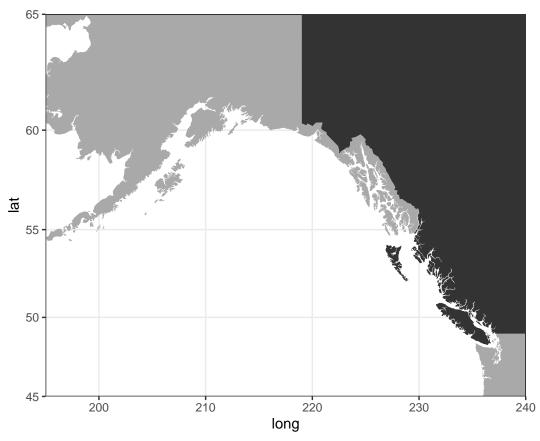

## 3.3.3.3 Low Resolution Pacific Coast Maps

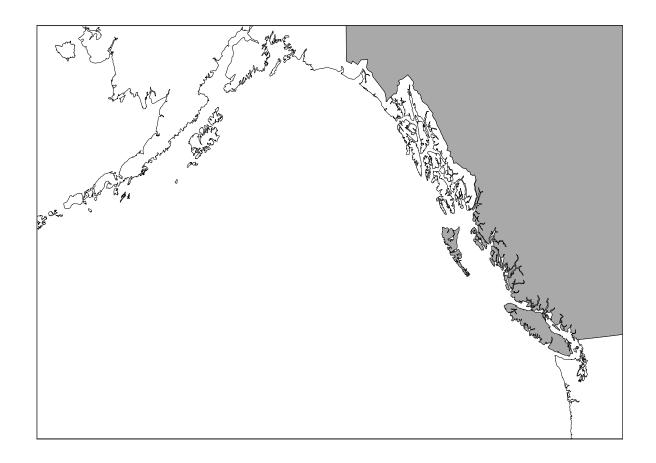

For lower resolution maps to represent larger scales you can use the maps from the maps and mapdata packages.

```
# playing with extent and colour
ggplot() +
  geom_polygon(data = subset(d, region=="Canada"), aes(x=long, y = lat, group = group)) +
  geom_polygon(data = subset(d, region=="USA"), aes(x=long, y = lat, group = group), fill="darkgrey") +
  coord_map(xlim=c(195, 240), ylim=c(45,65))+
  theme_bw()
```

# 3.4 Dates and Times in R
